

Internship Task

Take-home assessment: Audio Notes Platform

What to build

A web platform where a user uploads an audio file and gets back a **transcript** and a **summary**.

1. User uploads an audio file of any length or size. It should comfortably handle a 2 minute recording or longer. It does not have to be a meeting.
2. The platform transcribes it using **Gnani's ASR API**.
3. It displays the transcript.
4. It displays a summary of the audio, generated by an LLM of your choice.
5. Past uploads are listed and can be reopened.
6. Use Nextjs for the frontend and Fastapi for the backend, Postgres DB, storage bucket and background jobs

Requirements

- **Deploy it.** Vercel, Render, Railway, Fly.io, a VPS, anything. We must be able to open a URL and use it without setting anything up.
- **Add an /architecture page inside the app.** A written explanation of how your system works: the flow from upload to transcript, where files live, how you handled long audio, what runs synchronously vs in the background, and anything you'd do differently with more time. Diagram optional, plain prose is fine. **Link your GitHub repo from this page.**
- **Handle failure visibly.** Uploads fail, APIs time out, files get corrupted. The user should always know what's happening.
- **Show progress.** A long file should not look like a frozen page.

Gnani ASR access

Sign up at gnani.ai. New accounts get **₹1,000 in free credits**, which is more than enough for this task. API docs are at docs.gnani.ai/api/STT/speech-to-text.

Try the ASR yourself first at app.gnani.ai/voice/speech-to-text to see how the transcription behaves before you design around it.

Read the docs before you start building. It will save you time.

Submit here: <https://forms.gle/dxXoTPSZkLuosQ7t5>

Deadline: Saturday 23:59 IST.

Note: Don't simply vibe code the assignment, because in the next round, you will be questioned from the code of this project. So, it is easy to identify a vibecoder and reject.
